# Empirical Study of Islamic Banks Versus Conventional Banks of GCC Dr. Imtiaz .P. Merchant<sup>1</sup> <sup>1</sup> University of Wollongong in Dubai. Received: 6 December 2011 Accepted: 31 December 2011 Published: 15 January 2012

#### 7 Abstract

Numerous precious researches that have been conducted at professional and academia level 8 have established Islamic banking to be superior and a viable manner of banking in terms of 9 profitability and stability. The objective of the study would be to analyze the performance of 10 Islamic banks and conventional banks during the crisis and after the crisis. The study will 11 further focus on finding the steps that have been taken by the banks so as to reduce the effects 12 of crisis. The study will be examined by comparing the performance of Islamic and 13 conventional banks based in the Gulf Cooperation Council (GCC) during the period of 2008 14  $\hat{a}$ ??" 2011 by deploying the CAMEL testing factors. A sample of 17 Islamic banks and 10 15 conventional banks were selected to study the objective. Using the 2 tailed t test, our study 16 found out that after crisis Islamic bank increased their LLR, while conventional banks 17 increased their LLR and EQTA. During the four year period of 2008 â??" 2011, Islamic banks 18 possessed adequate capital structure but have recorded lower ROAE and poor management 19 efficiency. Asset quality and liquidity for both the modes of banking system have not recorded 20 any significant difference. 21

22

23 Index terms— Islamic banks, Conventional banks, financial crisis, after crisis, CAMEL.

# 24 1 Introduction

slamic banking has been a growing globally at a very fast pace. It all started with the early 70's and since 25 then the world has witnessed their enormous growth. Though the foundations of Islamic banking were placed 26 decades ago, researcher termed Islamic banks as a way of banking that would serve the refurbished conventional 27 banking products in a misleading way. However, in the course of time, numerous academia and researchers have 28 believed Islamic banking to be a viable way of dealing in finances. This is evident from the fact that Islamic 29 banks and financial institutions have increased significantly in Middle East, South East Asia, Far East Asia and 30 the European regions. Banks in these regions have not only started operating the full fledge Islamic banks but 31 have also started operating Islamic windows in a conventional banking framework. Some of these Islamic windows 32 provider are HSBC, Standard Chartered and Citi. 33

34 The recent global crisis of 2008 -2009 have increased the importance of creating a stable and solidifying financial 35 system ensuring that the investors Author : B.COM (Finance), University of Wollongong in Dubai. MSc (Finance, 36 Accounting and Management), Bradford university School of Management". E-mail: merchant.imtiaz@gmail.com industry. Globally, an effort is carried out to reduce the risk that make the banking industry fragile and also 37 set up an efficient way of banking thereby increasing efficiency in the financial process and transaction. Islamic 38 banks and conventional banks have been adopting different strategies that would help them to increase their 39 profitability levels and achieve a higher market share. With the start of the recovery in the financial system, 40 banks are adopting different ways to settle the effects of financial crisis. But an important question arises. 41 With the adoption of different strategies and principles, does this affect the performance of Islamic banks and 42

43 conventional bank? Therefore, this paper will ahead compare the performance of Islamic banks with conventional

44 banks over the period of 2008 -2011 in the Gulf Cooperation Council (GCC). Further, the objective of the paper 45 would be to understand and analyze the changes with respect to the behavior of the Islamic and conventional

<sup>46</sup> banks after the end of the crisis. This would help us understand the ways that the banks have adapted to offset

47 the criticality that have been developed during the period of crisis.

# <sup>49</sup> 3 Differences Between Islamic and Conventional Banking

Banks have devised several ways that would assist them in generating profit. Conventional banks have assured 50 strategies and tactics that aid them to generate profit and be competitive in the industry. Mohammad et al 51 ??2008) states that conventional banks generate income from the spread amid the interest rate charged to the 52 debtors and the interest rate paid to the depositors. There are other set of conventional banks that indulge in the 53 non-traditional approaches that are in the form of deposit and lending principle. Deposit and lending activities are 54 carried out by institutions such as credit card institutions or mortgages dealing institutions. Earning generated 55 by undertaking such activity is through selling loans and then earning profits by charging the debtors with fees. 56 In contrast, the Islamic method of banking and its associated ideologies are resulting from the Holy Quran, 57 the traditions of Prophet Muhammad (PBUHP) and through the narrations of followers of different Fiqh. Fiqh 58 is well-defined as the presentation of sharia that is assumed to be of different schools of thought. The maturity of 59 Islam with time led to development of diverse I feel safe and do not lose the confidence in the banking schools of 60 thoughts i.e. Hanafi, Maliki, Shafi'I, Hanbali and Ja'afariya. Islamic banking arrangement is a lone and dynamic 61 62 execution of the Islamic legal code or Sharia. Islamic banks are repeatedly branded as a banking system that 63 forbids interest on loans and deposits. But this is not the only difference between Islamic and conventional bank. Though Islamic bank rejects and disallows the notion of interest on transactions, Islamic banks do not discard 64 the time value of money. It provides the financier the benefits of a suitable income on money. The following 65 explains the idea: 66

Firstly, the benefit received by the institution by lending the fund to the borrower for a specific time is not predetermined. This means that the benefit received by the lender will be a share in the revenue that has been earned from the undertaking carried out by the borrower. Secondly, in event of financing for acquiring tangible goods by the investor through sales or lease, the investors might compensate themselves for the opportunity sacrificed. Profits that are therefore derived from the sale or the lease reflect the time value.

The fundamental justification of Islamic banking is that individuals are not considered as creditors; relatively they are associates in any undertakings. As per the Islamic code of conducts individuals are refrained from dealing in any kind of transactions that comprise of Riba (interest). Khan (2012) state that Islamic banks lend funds to the debtors on the basis of Profit and Loss sharing system (PLs). Under this arrangement, the associates agree to share the profits and losses on the basis of share in the capital and the efforts undertaken. Hence, PLs concept does not favor the fix rate of return on the asset. This theory therefore rejects the notion of conventional bank system as Islamic banks do not commit any rate of return. It is also important to note that transactions

<sup>79</sup> in the Islamic method of banking is supported and backed by tangible assets. Conventional banks on the other

 $_{\rm 80}$   $\,$  hand deal with fiscal transactions with the backing of any assets. (Ali, 2005)

#### <sup>81</sup> 4 Literature Review

Various studies have been conducted to compare the performance of Islamic banks with that of conventional

banks. However, the volume of such researches has been limited. This is due to the fact that the data of Islamic
banks have been unavailable due to their recent growth. This section will focus and highlight the recent researches

that have been conducted. This will give an idea as to the performance of Islamic and conventional banks in the different regions during the different periods.

Parashar and Venkatesh (2010) compared 6 Islamic banks and 6 conventional banks in the GCC region for a period of 2006 -2009 utilizing 6 ratios namely capital asset ratio, cost to income ratio, return on average assets, return on average equity, equity to total assets and liquid assets to total assets. Their study shows that during the global crisis Islamic banks suffered more in terms of capital ratio, leverage and return on average equity, while conventional banks exhibited a poor performance in return on average assets and liquidity. Further, during the

<sup>92</sup> 4 year period of 2006 -2009, Islamic banks have outperformed conventional banks in the region.

Zeitun (2012) directed a study on the GCC for a period of 2002 -2009, to assess the factors that affect the Islamic bank and conventional banks. The study included a sample of 38 conventional banks, and 13 Islamic banks. The factors that were studied were foreign ownership, bank specific variable and macroeconomic variables. Some interesting results were found. Cost to income ratio and performance of the banks held a negative correlation for Islamic banks. The size of the banks supported the economies of scale utilizing the ROE for Islamic banks.

GDP was found to be positively related, while inflation negatively related to the banks performance.
In a study piloted by Jaffar and Manarvi (2011), the authors study a sample of 5 Islamic banks and 5

conventional banks in the Pakistan for a period of 2005 -2009. The authors found that Islamic banks performed

well in capital adequacy and liquidity while conventional banks performed better in earning and management
 quality. Asset quality remained the same in Islamic banks and conventional banks.

Olson and Zoubi (2008) studied and compared the Islamic and conventional banks in the GCC over a period of 2000-2005. Utilizing 26 financial ratios, the authors found that profitability between Islamic and conventional banks is not much different. However, Islamic banks are found to be less efficient and are operating with higher risk. The reason for Islamic banks are risky is Islamic banks uphold funds that are to be used in case of bad loans. Conventional banks on the other hand offer deposits fund that are completely predetermined by interest rates whereas Islamic banks offer deposit funds that are similar to equity as they share diverse types of risk.

Ansari and Rehman (2011) conducted a study on the performance analysis of Islamic and conventional banks based in Pakistan for the period of 2006 -2009. By utilizing 18 different financial ratios which represented

112 profitability, liquidity, risk and solvency, capital adequacy, deployment ratio and operational efficiency, the authors

found out that in comparison to conventional banks, Islamic banks were highly liquid and less operational efficient.
Authors also found out that Islamic banks were less risky than conventional banks.

115 IV.

#### <sup>116</sup> 5 Methodology and Data

In order to achieve answers to the desired set aims and objectives, it is important that we follow a technique 117 that is useful in gathering and analyzing the data. The paper will deal with the quantitative study. Our paper 118 deals with 6 performance parameters, which will assist us in gauging the performance of Islamic and conventional 119 banks. This performance parameter will be collectively known as CAMEL. The CAMEL framework is a set 120 of variables that include the capital adequacy, asset quality, management quality, earnings and liquidity. It is 121 widely believed that the financial performance of the banks should take into the account the capital adequacy, 122 earnings and liquidity management of the banks. Asset quality can assist the bank in providing and scrutinizing 123 the risk associated with the bank's portfolio. Management quality can be judged by assessing the cost reducing 124 capability of the management and simultaneously increasing profits. The above mentioned are the performance 125 parameters, but to achieve the desired results the paper would be utilizing 6 ratios that define their respective 126 parameters. These are mentioned below: a) Capital Adequacy : 127

The measurement of capital adequacy is an important parameter to be measured by the banks. It can assist 128 the bank and it management in understanding the shock captivating capability during times of risk. In our 129 study, capital adequacy will be measured by using the Equity to total assets ratio (EQTA) (Vong & Chan, 2009). 130 EQTA is reflected to be a degree of capital adequacy and will support our study in understanding the safety 131 and financial reliability of the banks. This ratio will help us in defining the magnitude of assets that have been 132 financed by owner's funds. The logic is that high EQTA ratio will aid the bank in providing a strong cushion 133 to increase its credit undertakings and lower the unanticipated risks. Samad (2004) states, that high level of 134 EQTA often supports the organization in charming asset losses. This implies that as the amount of the equity to 135 back the assets of banks depresses, the bankruptcy risk of the bank intensifies. Also, Hassan and Bashir (2003) 136 state that constant lowering of EQTA hints to invitation of risk in the banks and therefore highlight the capital 137 adequacy of the bank. Hence, we assume this ratio to be as higher as possible. 138

b) Asset quality : Asset quality will help the bank in increasingly understand the risk with respect to the 139 exposure of a bank to the debtors. Asset quality in our study will be measured by loan loss reserves (LLR). 140 141 LLR can be defined as an indicator to evaluate the value of loans by a bank. In other words, this performance 142 parameter will benefit the bank in understanding the amount of funds that have been reserved by the banks in 143 event of bad loans. This suggests that LLR is an assurance to cover the bad and doubtful loans of the bank. Since this ratio delivers an image of the sum of the provision that have been kept aside for bad and doubtful 144 loans, banks should focus and ensure that they uphold low provision for bad loans. Banks that maintain high 145 provision for bad loans should be concerned as this will signal towards future losses. Hence, in our study we will 146 assume this ratio to be as lower as possible. 147

# <sup>148</sup> 6 c) Management quality :

This measure of performance will shed light on the superiority of the management. The duty of the management 149 is to safeguard that the banks operation runs in a smooth and decent manner. Very often, the banks superiority 150 in terms of management is decided by the skill and ability of the management to control the cost and increase 151 productivity, ultimately achieving higher profits. Hence, cost to income ratio (COSR) will be utilized to measure 152 the management quality. COSR can be extensively defined as the cost incurred by the organization to generate 153 a dollar of income. COSR is one of the premium ratios to capture the management competence of the bank. By 154 controlling the cost, it is meant to control the overhead cost that is sustained to run a bank. Hence, in our study 155 we expect the COSR to be as lower as possible. 156

# <sup>157</sup> 7 d) Earnings :

Earnings being one of the performance parameters highlights on the banks prevailing and forthcoming activities with respect to its earnings. It essentially aids the bank in concentrating on the loss gripping capacity, determining the level of its earnings and revenue as well as the funds available for rewarding its shareholders. Our study would

be employing two performance measures to determine the profitability of the banks. These are return on average 161 assets (ROAA) and return on average equity (ROAE). ROAA fundamentally sheds light and specifies the ways 162 that management exploits its assets to generate earnings. ROAA is also an indicator of operational efficiency 163 (Petersen and Schoeman, 2008). In simple words, ROAA will deliver us with information on the amount of 164 income generated from the each unit of asset on an average. ROAE on the other hand is a measurement that 165 contributes in understanding the working of the management of the organization with respect to the earnings or 166 income generated from the owner's equity. ROAE can be defined to measure the returns on the equity holders 167 in order to evaluate the growth on their investments. Petersen and Schoeman (2008) state that the banks 168 maintain sufficient capital to avoid failure, but banks should ensure that they do not hold extra capital. Hence, 169 a association can be established where higher the equity capital, the lower the ROAE. 170

# $_{171}$ 8 e) Liquidity :

This parameter of performance can aid the banks and establishments to evaluate the risk faced by the banks in 172 case of an unprecedented and unforeseen circumstance that can be the main reason for an insolvency of bank. To 173 174 assess the liquidity of the banks, we would be using the net loan to total assets (NLTA). NLTA can be defined 175 as the amount of assets that have been engaged in loans. Hassan and Bashir (2003) found that the NLTA should be as lower as possible. High NLTA will often result in inferior liquidity standards of the bank. The only reason 176 being, that high NLTA indicates that the bank is engaged highly in lending and this may have adverse effects as 177 178 the bank might face huge risk of defaulters. Hence, in our study, we expect this ratio to be as lower as possible. The study will apply the t test to test the differences between the mean ratios of Islamic and conventional 179 This t test have been performed using the Microsoft excel. The data utilized for the study will by a 180 banks. pooled times series data. Pooled time series data is a type of data set that contains information on variables 181 that are stretched over a period of time. This study will utilize the data for 5 countries in GCC i.e. Bahrain, 182 Kuwait, Kingdom of Saudi Arabia, Qatar and United Arab Emirates. Oman will not be included in the study 183 184 as Oman does not engage in Islamic banking at the moment. The study will consist of 17 Islamic banks and 10 185 conventional banks. Though there is a difference in the sample size, an attempt has been carried out to keep the asset size of Islamic banks as similar as possible with that of conventional banks. The period of the study will 186 be from 2008 -2011. Alexa at al. ??2011) states that though the period of 2010 -2011 has still been influenced 187 by the effects of global financial crisis, the financial system of the economies has been improved when compared 188 to the period of financial crisis. 189

Hence, to understand the analysis in depth, this study will be further divided into 2 phases that would comprise 190 191 of during crisis phase (2008 - 2009) and recovery phase (2010 - 2011). Also, several hypotheses have been developed to test the difference in means for the period of during crisis (2008 - 2009) and recovery phase (2010 - 2011). This 192 193 will give our study a good idea of how Islamic and conventional banks have controlled their financial situation 194 during the crisis and after the crisis. The data for the study will be acquired from Bankscope. Bankscope is a 195 database that has gathered data for more than 11000 banks under the supervision of International bank credit analysis limited. The next section will deal with the performance of Islamic and conventional banks over the 196 197 period of 2008 -2011. were well capitalized during the 4 year period. Furthermore, the average ROAE for Islamic banks measured at 6.58% which is lower as compared to 11.84% of conventional bank. The finding of COSR is 198 also significant as the COSR for Islamic banks is 53.62% for Islamic banks, which is much higher when compared 199 to 34.47% of conventional banks. Hence, it is concluded that during the four year (2008 -2011) which takes into 200 account the effects of crisis and the recovery phase, Islamic banks were well capitalized, and were performing 201 with low ROAE. High COSR for Islamic banks indicated that Islamic banks have been not able to control the 202 cost which can be seen as one of the management inefficiencies. It can be also said that high cost of Islamic 203 204 banks would have led to low profitability. ROAA for Islamic banks have been low on an average measuring at 0.89% when compared to 1.69% for conventional banks. LLR for Islamic banks has been found out to be 3.55%205 which is marginally higher than that of conventional bank's 3.34%. NLTA for Islamic banks is 58.01% which is 206 lower when compared to 59.02% for conventional banks. 207

There are no statistical significant differences found in NLTA, LLR and ROAA of Islamic banks and conventional banks. This does not imply that the results can be ignored. However, the liquidity and asset quality of Islamic banks and conventional banks had no noticeable differences. To better understand the performance of Islamic and conventional banks, the study will be further more divided in 2 phases namely during crisis and recovery phase. The data exhibited in table 2 describes the performance of Islamic banks during the crisis and after the crisis or the recovery phase. As observed in the table 2, applying the paired sample t test, there is only one variable that is statistically significant namely LLR.

215 Note : P value of \* (p<0.05) refer to statistical significant at 5 percent level respectively LLR has increased 216 from 3.03% during the crisis to 4.07% in the recovery phase. This means that the credit and risk management for 217 Islamic banks has not been to the mark and banks have been forced to increase their reserves so as to compensate the default that has been accumulated during the crisis. Other ratios that have declined are: EQTA (from 24.83%218 to 23.93%), ROAA (1.01% to 0.77%), ROAE (6.64% to 6.52%), COSR (57.81% to 49.43%) and NLTA (59.02% 219 to 56.99%). While the decline in COSR is a positive indication for Islamic banks which suggest that management 220 efficiency measured in terms of controlling cost has improved. Thus banks can increase their profit margin. NLTA 221 is expected to be as lower as possible as this indicates towards a better liquidity management of Islamic banks. 222

Decline in NLTA suggest that total assets that are tied to loans have improved after crisis denoting a strong defense after the crisis. This can be interpreted as the amount of assets that have been tied in loans has been less. Islamic banks have increased their liquidity.

The reason being that unlike their counter parts, Islamic banks are not allowed to borrow any funds from the central bank. Also, Islamic banks refrain from investing in any financial instruments that are interest related. Hence, in such instances, Islamic banks maintain high liquidity and a strong line of defense. However, it should be noted that high liquidity can leads to lower profits as banks have more of assets that play role of liquid assets and hence results in missing the investment opportunities. This effect is clearly evident from the declining figures of ROAA and ROAE. Thus Islamic banks are paying the opportunity cost of increasing liquidity. However these results are not significant.

# <sup>233</sup> 9 VII.

Conventional Banks: During Crisis (2008 - 2009) v/s Recovery Phase ?? 2010 - 2011) The table ?? describes the 234 performance of conventional banks during the crisis and in the recovery phase. The results have been obtained by 235 236 applying the paired sample t test. It is observed that LLR has increased from 2.95% during crisis to 3.74% in the recovery phase while EQTA has increased from 12.92% during the crisis to 14.80% in the recovery phase. These 237 findings are statistically significant. From the findings it can be said that conventional banks have been better 238 239 capitalized in the recovery stage when compared to period during the crisis. After the crisis, conventional banks have taken up the task to provide and safeguard their system. When a bank has a strong capital structure that 240 safeguards their position, the bank will have to rely less on external sources of funding. Also, increased EQTA 241 can assist the bank to indulge in lending, which would ultimately increase their profits. Subsequently, it would 242 also lead to increased shock absorbing capacity for the institution. On the other hand, similar to the findings 243 of Islamic banks, conventional banks have also increased their LLR so as to compensate the defaults that have 244 aroused during the crisis. In this way, banks would be able to identify weak loans and possible bad debts that 245 246 would eventually help them increase their profitability.

Table ??: Conventional banks during crisis and recovery phase Note : P value of \* (p<0.05) refer to statistical 247 significant at 5 percent level respectively However, the following variables have increased: ROAA (from 1.69% to 248 1.70%) and COSR (from 34.25% to 35.49%) while the following variables have decreased: ROAE (from 12.07% 249 to 11.61% and NLTA (from 59.91% to 58.14%). These variables do not hold any results that are statistical 250 significant. Hence it can be concluded that after crisis, the LLR for Islamic banks have increased so as to ensure 251 that they are successful in offsetting the financial loss suffered during the period of crisis. While conventional 252 253 banks have also increased their LLR and have been highly capitalized after crisis. These steps clearly show that conventional banks and Islamic banks are taking preventive measures so as to offset any dangers that act as 254 255 hindrance to their operations. Our findings do not present any major changes in profitability of both the banks.

256 Furthermore, the study will test the various hypothesis developed by applying the independent two tailed t test 257 to check the differences in means for 6 financial ratios during the crisis and in the recovery phase. For example, our null hypothesis would state that there haven't been any difference between the meansEQTA of Islamic banks 258 259 and mean EQTA of conventional banks. Subsequently, our alternate hypothesis would state that there is a significant difference between the mean EQTA of Islamic banks and the mean EQTA of conventional banks. We 260 investigate the capital adequacy using the following hypothesis: H 0: Islamic EQTA = Conventional EQTA H 261 1 : Islamic EQTA Table ?? : Islamic and conventional banks EQTA during crisis and recovery phase Note : P 262 value of \* (p<0.05) refer to statistical significant at 5 percent level respectively EQTA assists in measuring the 263 capital adequacy. Table ?? shows that the Islamic bank's EQTA mean declined from 24.83% during crisis to 264 265 23.93% in the recovery phase. While the ratio of conventional banks rose from 12.92% during the crisis to 14.80%266 in the recovery phase. The null hypothesis of mean EQTA of Islamic banks equal to mean EQTA of conventional banks is rejected at 5% alpha during the crisis and the same is also rejected for recovery phase. Subsequently the 267 alternate hypothesis is accepted for both the periods. Our findings show that Islamic banks fared higher than 268 conventional banks for the EQTA measurement. This implies that Islamic banks were well capitalized during the 269 crisis and the recovery phase when compared to conventional banks. 270

The next set of hypothesis will assist in examining the asset quality. The hypothesis hence formed is: We 271 test the null hypothesis that the mean LLR of Islamic banks equal to the mean LLR of conventional banks. On 272 examining the table 5, we find that the mean LLR of Islamic banks was 3.03% during the crisis and increased 273 to 4.07% in the recovery phase. On the other hand, the mean LLR of conventional banks was 2.95% during the 274 crisis and increased to 3.74% in the recovery phase. Hence, at 5% alpha, we fail to reject the null hypothesis of 275 276 mean LLR of Islamic banks equal to mean LLR of conventional banks for both the periods. This implies that 277 there is no significant difference in the asset quality of Islamic banks and conventional banks during the crisis 278 and the recovery phase. We examine the following set of hypothesis to assess the management efficiency: H 0 279 : Islamic COSR = Conventional COSR H 1 : Islamic COSR Table 5 : Islamic and conventional banks COSR during crisis and recovery phase Note : P value of \* (p<0.05) refer to statistical significant at 5 percent level 280 respectively As exhibited in table 5, the mean COSR for Islamic banks was 57.81% during the crisis and declined 281 to 49.43% after the crisis. On the other hand, the COSR for conventional banks stood at 34.25% during the crisis 282 and witnessed an increase resulting to 35.49% after the crisis. The null hypothesis of mean COSR of Islamic 283 banks equal to the mean COSR of conventional banks is rejected at 5% significance for both the periods and 284

subsequently the alternative hypothesis is accepted. It can be therefore implied that the efficiency to control cost was better in conventional banks than in Islamic banks. This indicates that conventional banks were much efficient in controlling cost and from the management perspective during both the periods.H 0 : Islamic LLR = Conventional LLR H 1 : Islamic LLR

We investigate the profitability of the banks using the following set of hypothesis: H 0: Islamic ROAA = 289 Conventional ROAA H 1 : Islamic ROAA Conventional ROAA Table ?? : Islamic and conventional banks ROAA 290 during crisis and recovery phase Note : P value of \* (p<0.05) refer to statistical significant at 5 percent level 291 respectively In the table 6, we find that the ROAA mean of Islamic banks declined from 1.01% during the crisis to 292 0.77% in the recovery phase. In contrast, the ROAA for conventional banks witnessed a marginal increase from 293 1.69% during the crisis to 1.70% in the recovery phases. The two tailed t test signifies that the null hypothesis 294 of the mean ROAA of Islamic banks equal to mean ROAA of conventional banks is failed to be rejected at 5%295 alpha for both the periods. This further implies that there has been no significant difference in the ROAA for 296 Islamic banks and conventional banks during the crisis or in the recovery phase. 297

The following set of hypothesis has been formed in order to examine the profitability. The mean ROAE 298 of Islamic banks during the crisis stood at 6.64% and marginally declined to 6.52% in the recovery phase. In 299 contrast, the mean of ROAE for conventional banks stood at 12.07% during the crisis and declined to 11.61% in 300 301 the recovery phase. The two tailed t test signifies that the null hypothesis of mean ROAE of Islamic banks equal 302 to mean ROAE of conventional banks is failed to be rejected at 5% significance level during the crisis and the 303 same is rejected for the recovery phase. This implies that Islamic banks provided the shareholder with increased returns during the crisis as compared to recovery phase since the lower performance of ROAE in the recovery 304 phase is significant as and when compared to ROAE for conventional banks. 305

We examine the liquidity of the banks through the following set of hypothesis H 0 : Islamic NLTA = Conventional NLTA H 1 : Islamic NLTA 8, we find that the mean NLTA of Islamic banks stood at 59.02%during the crisis and declined to 56.99% during the recovery phase. In contrast, the mean NLTA of conventional banks measured at 59.91% during the crisis and declined to 58.14% in the recovery phase. The null hypothesis of no difference between the mean NLTA of Islamic banks and the mean NLTA of conventional banks is failed to be rejected at 5% significance during the crisis and the recovery phase. This indicates that there was no difference

in the liquidity of Islamic banks and conventional banks during the crisis or during the recovery phase.

313 VIII.

# 314 10 Conclusion

Our analysis shows that during the four year period of 2008 -2011, EQTA, ROAE and COSR were found to be significant. While Islamic banks were found to deliver high in terms of EQTA, conventional banks were found to perform well in ROAE and COSR. This indicates that over the four year, Islamic banks were better capitalized but have performed low in terms of profitability. COSR as an indicator of management efficiency was found to be poor for Islamic banks. Consistent high COSR has led to low profitability levels of Islamic banks after the crisis.

Further, we analyzed the performance of Islamic and conventional banks before and after crisis. It was found 321 that for Islamic banks, LLR as a measurement of asset quality has significantly increased indicating a risky 322 323 portfolio after crisis while on the other hand, LLR and EQTA for conventional banks after crisis have increased 324 indicating of a risky portfolio and improved capital adequacy of conventional banks. The behavior of Islamic banks and conventional banks might have been to increase the LLR so as to offset the default on loans by 325 customers that had been accumulated during the crisis. Increased LLR indicates of banks potential to identify 326 weak loans and hence increasing profitability. However, we find neither Islamic banks nor conventional banks have 327 been able to generate significant increased profits after crisis. Moreover, conventional banks have also increased 328 their EQTA so as to increase their shock absorbing capacity. This would have been again due to increased losses 329 for conventional banks during crisis. The increases in capitalization can also assist the banks in increase their 330 lending activities and ultimately increase their profits. 331 Comparing the performance of Islamic and conventional banks during the crisis and in the recovery phase, 332

Every study has scope for further study. This study has been performed on the banks based in the GCC. To get a better understanding it would be interesting to analyze similar objectives by including banks from other countries. This will simultaneously increase the sample size which would provide a more detailed outlook on the performance of the two banking systems.
